

The artifact was a word counter with the intent of counting the number of times an item appears in a list file. It was created for a project where we needed to create a program that would count the amount of times fruits and vegetables would appear in the list file. It was created February 17th, 2026. The inclusion of the artifact is to show an understanding of modular and portable programming as well as the ability to program in C++. The artifact was improved by adding an interactable menu to allow the user to load other files as well as select what they want to do without having to go through a linear process. There were also removals of redundant code and some minor fixes to the code. I believe that I have met the intended course outcome that I had set out in module one.

While I was improving the program, I was looking back at my code to see if I still understood my code and my thought process on creating the code. While there were some decisions that I believe were suboptimal for my code, I still understood that someone who was learning the language could make such mistakes. Such as when counting all items in the list, the first word would not be counted, at the time I was not sure why and added an extra count of the item after it was finished counting all instances of the item, however while revising the code I realised that when the item was first counted, I initialized the variable keeping track of the item count as zero instead of one, leading to the first item not being counted. When revising the code, the biggest challenge was recalling how to program in C++, as I have not programmed in that language in a while due to classes being programmed in different languages.
